

# Crop Simulation Modeling

The current agricultural production system is challenged by weather, climate extremes, variability, and economic risks.

There is pressure to grow more healthy food using sustainable practices.

At the same time, technology is rapidly improving with new sensor technologies, the Internet of Things, edge computing, and remote sensing.

The amount of data collected for agricultural production systems is exponentially expanding, providing opportunities for data analytics for strategic and actionable decisions.

The modeling of the ecosystem can play a major role in helping to understand the interaction between **Genotype, Environment, and Management (G \* E \* M)** and to provide alternative management options that **increase crop yield and quality, optimize resource use, and minimize environmental impact for long-term sustainable agricultural production.**

# Model Definition

A model is a simplified representation of a system or a process. A model is a computer program, which describes the mechanism of the process or a system.

Modeling is based on the assumption that any given process can be expressed in a form of a mathematical statement or set of statements or a sets of statements to depict the real world system.

## Discrete Model

The state variables change only at a countable number of points in time. These points in time are the ones at which the event occurs/change in state.

Example: Statistical model

## Continuous Model

The state variables change in a continuous way, and not abruptly from one state to another (infinite number of states).

Example: Crop Simulation Model

## Simulation Modelling

Simulation modelling is the process of creating and analyzing a digital prototype of a physical model to predict its performance in the real world.

# Crop Simulation Models

- The crop simulation models are in fact a simple and meaningful representation of a crop, construed as systems research tool, which aid in solving the problems associated with agricultural crop production and these crop simulation models are needed to distill the knowledge obtained through field-based experimentation and observations.
- It provides a platform for interdisciplinary collaboration. Also, the systems approach adopted by crop simulation models helps in solving problems arising from crop production.
- Operationally, the crop models require input data pertaining to and limited to crop type and varieties, soil types and characteristics; weather data and agronomic practices.
- Crop simulation models are used to gauge the effects of soil, climate, and crop management practices on growth and development of crops; and agricultural productivity and sustainability of the agricultural production system.
- The use of crop simulation models for agricultural research greatly reduces the cost and time involved in the field experiments. This is because the results obtained for one location or season can be extrapolated to other locations and seasons.
- The development of crop simulation models, along with the application of decision support system approaches, greatly aids in augmenting resource use and agricultural productivity; minimising the environmental impacts borne out of agricultural practices; and mapping the yield gaps.

There are several tool of systems related to computer and information technology can help in solving agricultural problems.

One such tool is crop growth simulation model.

These models are based on quantitative understanding of the underlying processes, and integrate the effect of soil, weather, crop, pest and management factor on growth and yield.

The process are

- crop physiological
- Meteorological
- soil physical
- chemical
- biological.

Depending upon the objective, knowledge base of various agricultural disciplines can be integrated in a crop model

# APPLICATIONS OF CROPMODEL

## Estimation of Potential Yields

Calibrated and validated model will predict the potential yield perfectly under no stress condition

## Estimation of Yield Gaps

Model will be used to estimate the yield gaps between

- potential yield and attainable yield
- potential yield and actual yield
- potential yield and farmers yield.

Assessment the principal causes, contribution and remedial measures for yield gap and bridging the yield gap.

## Yield Forecasting

Calibrated and validated models are useful for yield forecasting, which will be useful for marketing of produce in right time at right place and at right price

# Limitations

- The crop models can only aid in improving our understanding about the agricultural production system, and they cannot replace field experiments altogether.
- Application of models developed for a region, require parameterization and calibration before being applied in other regions

# Agriculture

The agricultural system is a **complex** system that includes many interactions between biotic and abiotic factors

Abiotic factors = Non-Living

Weather/climate

Soil properties

Crop management

Crop and variety selection

Planting date and spacing

Inputs, including irrigation and fertilizer

Biotic factors

Pests and diseases

Weeds

Soil fauna

Socio-economic factors

Prices of grain and byproducts

Input and labor costs

Policies

Cultural settings

Human decision making

Environmental constraints

Pollution

Natural resources

## Management

Some of these factors can be modified by farmer interactions and intervention, while others are controlled by nature.

Senescence is the process of aging or growing old. It can refer to the gradual decline in an organism's functional characteristics that occurs after its development phase. It can also refer to the permanent arrest of cell division in a cell, which occurs when a cell ages but does not die

## Key processes involved in crop growth and development and their interactions with the crop system

A model is a mathematical representation of a real world system.

## What is a crop simulation model?

- Crop simulation model is a combination of mathematical equations and logic used to conceptually represent a simplified crop production system.
- **Simulation** means that model acts like a real crop, gradually germinating, growing leaves, stem and roots during the season.
- In other words, simulation is the process of using a model dynamically by following a system over a time period.

Crop simulation models integrate the current state-of-the art scientific knowledge from many different disciplines, including

crop physiology

plant breeding

agronomy

agrometeorology

soil physics, soil chemistry, soil fertility plant

pathology, entomology economics and many others.

## Simple Model

Air temperature

==>Vegetative and  
reproductive development

Solar radiation

==>Photosynthesis and  
biomass growth

Development \* Biomass = Yield

**Yield =  $f$  (Development, Biomass)**

Development =  $f$  (Environment, Genetics)

Biomass =  $f$  (Environment, Genetics)

Environment =  $f$  (Weather, Soil)

Other factors:

management

stress (biotic and abiotic)

# Model Frame work

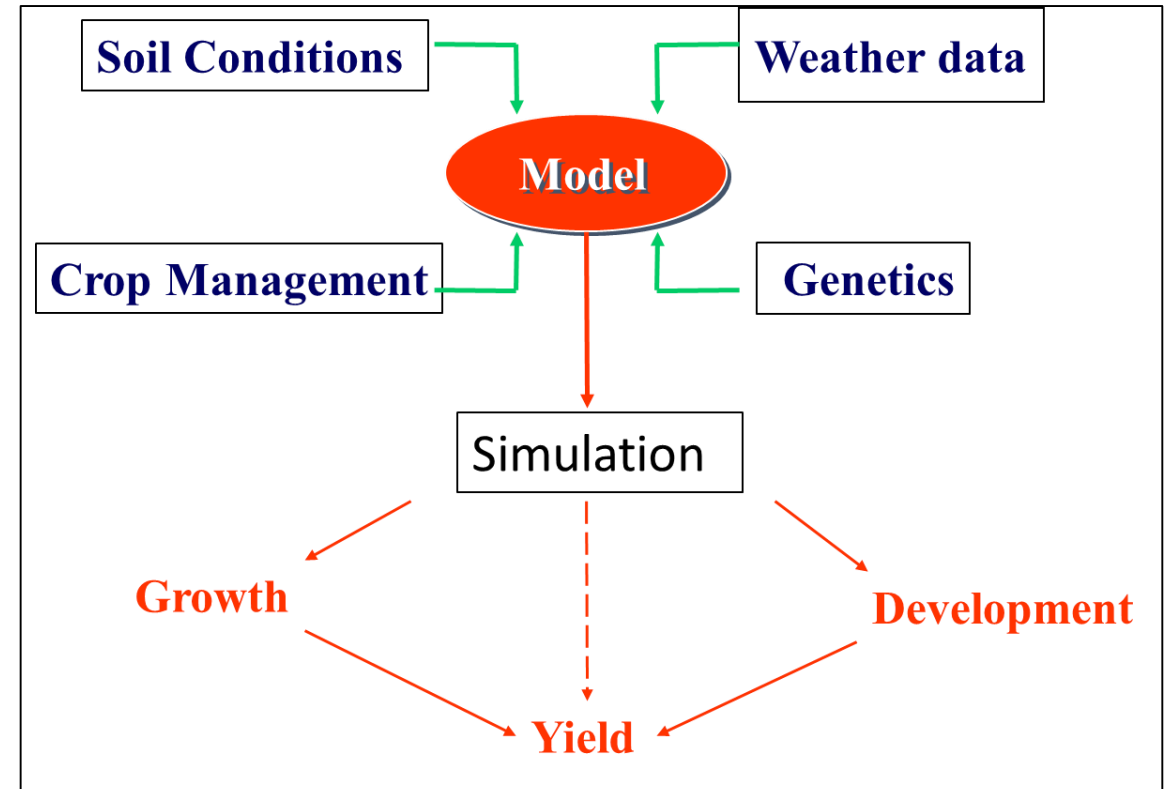

Crop simulation models in general calculate or predict *crop growth and yield* as a function of:

Genetics

Weather conditions

Soil conditions

Crop management

# Agricultural Production

Potential production

Water-limited production

Nitrogen-limited production

Nutrient-limited production

Pest-limited production

Other factors

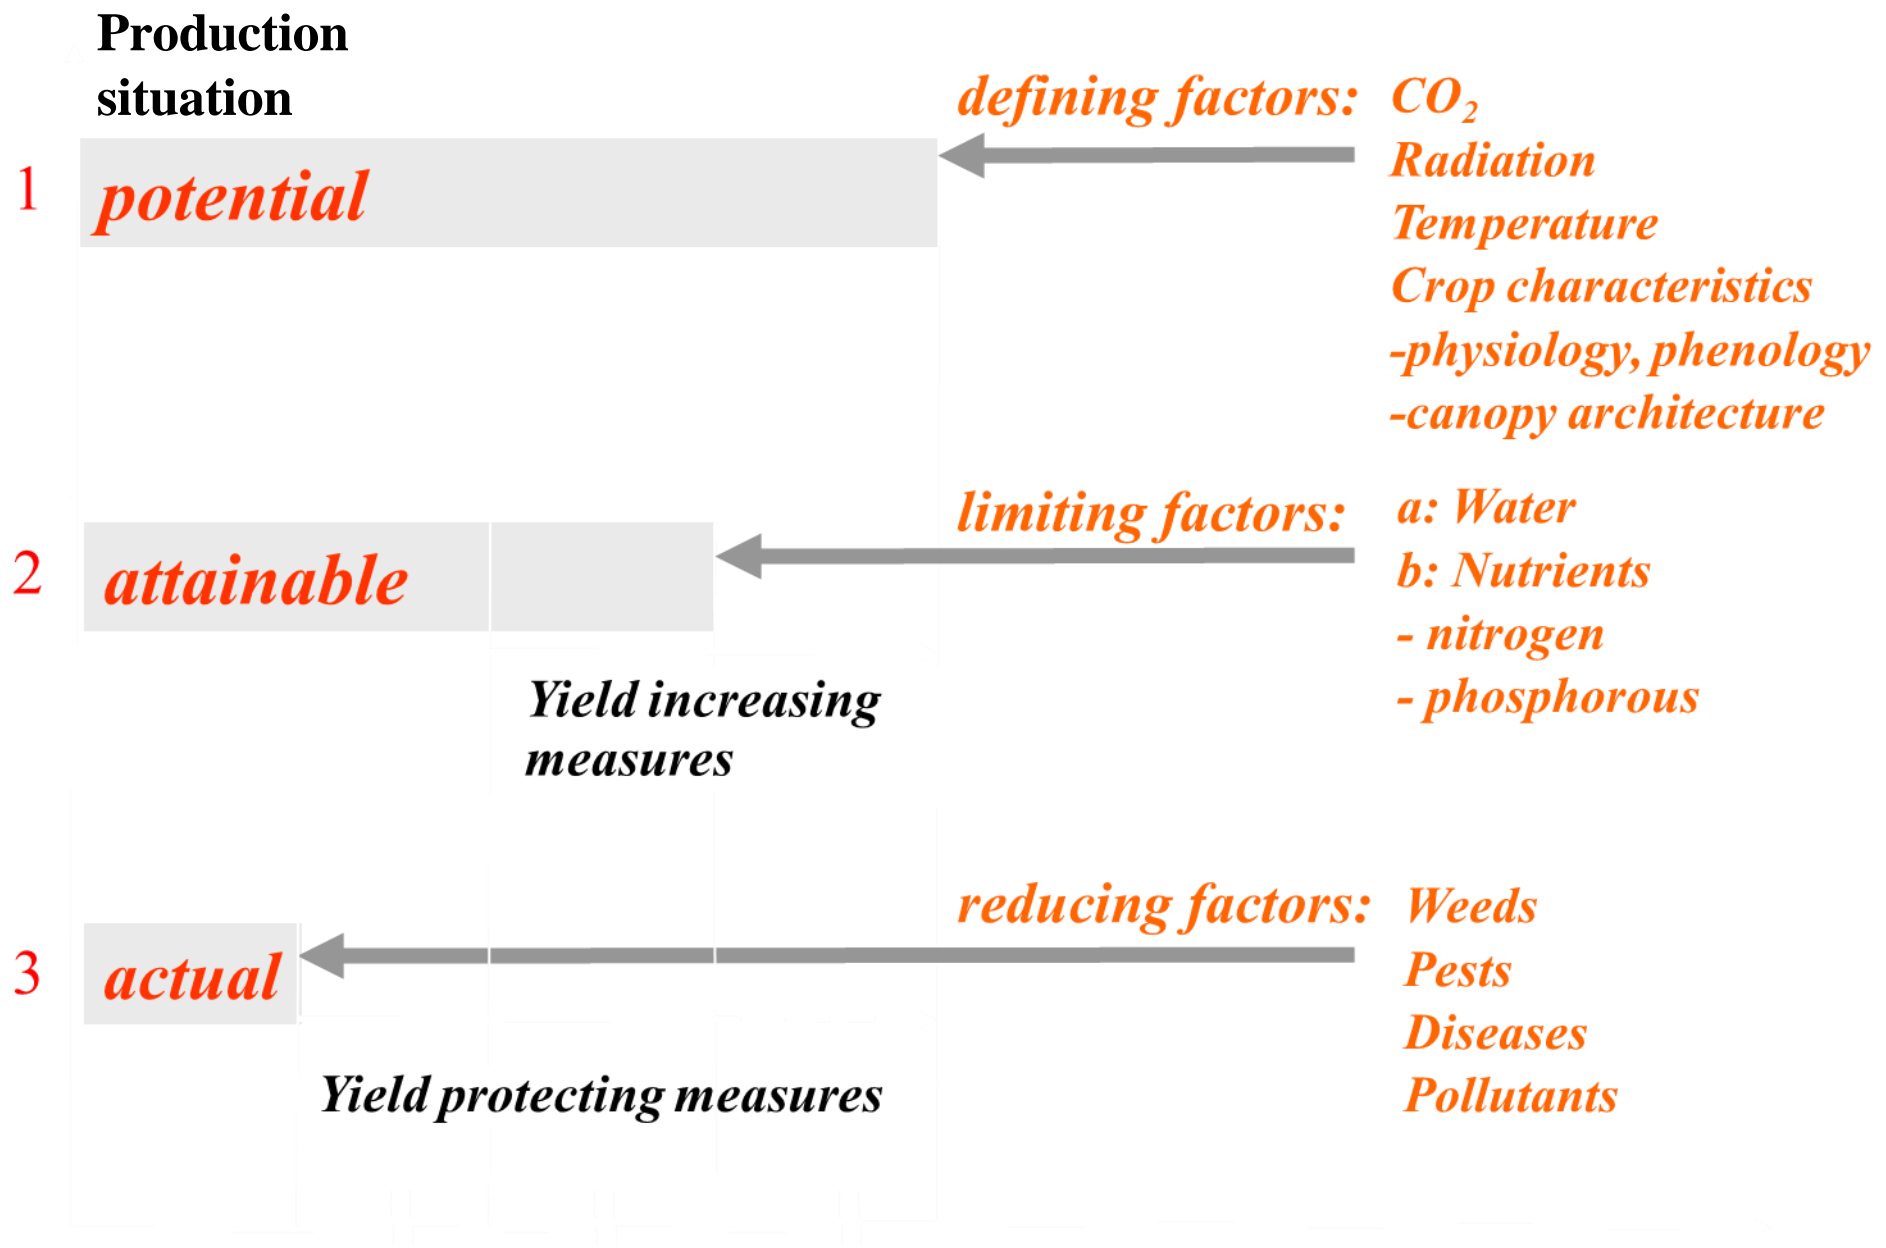

- Extreme weather events

- Salinity

Complexity

Real World

Source: World Food Production: Biophysical Factors of Agricultural Production, 1992.

# Crop Simulation Models

Require information (Inputs)

- Field and soil characteristics
- Weather (daily)
- Cultivar characteristics
- Management

Model calibration for local variety

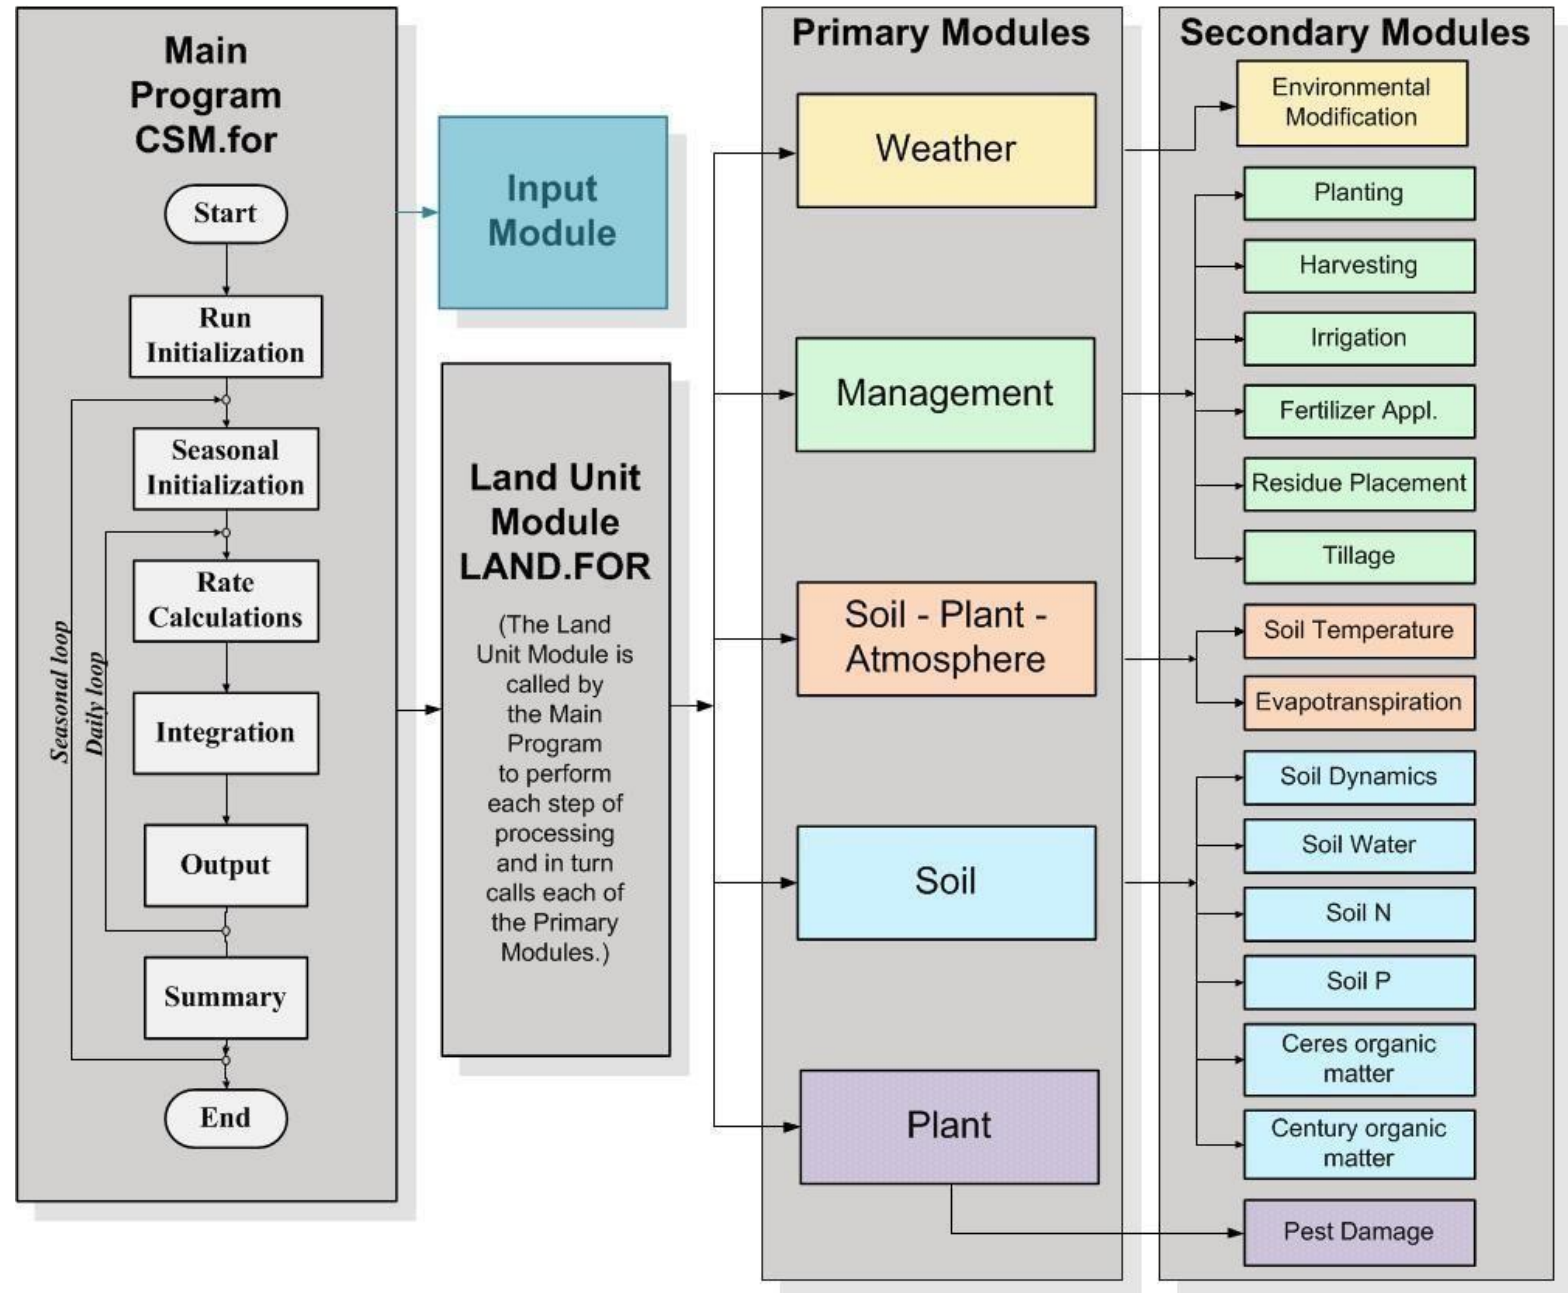

Model evaluation with independent data set

Can be used to perform “what-if”  
experiments

# Starting the DSSAT v4.5 model from your Desktop

Start → programs → DSSAT45 → DSSAT45

Main window of DSSAT45

## Menu Items under DSSAT 45

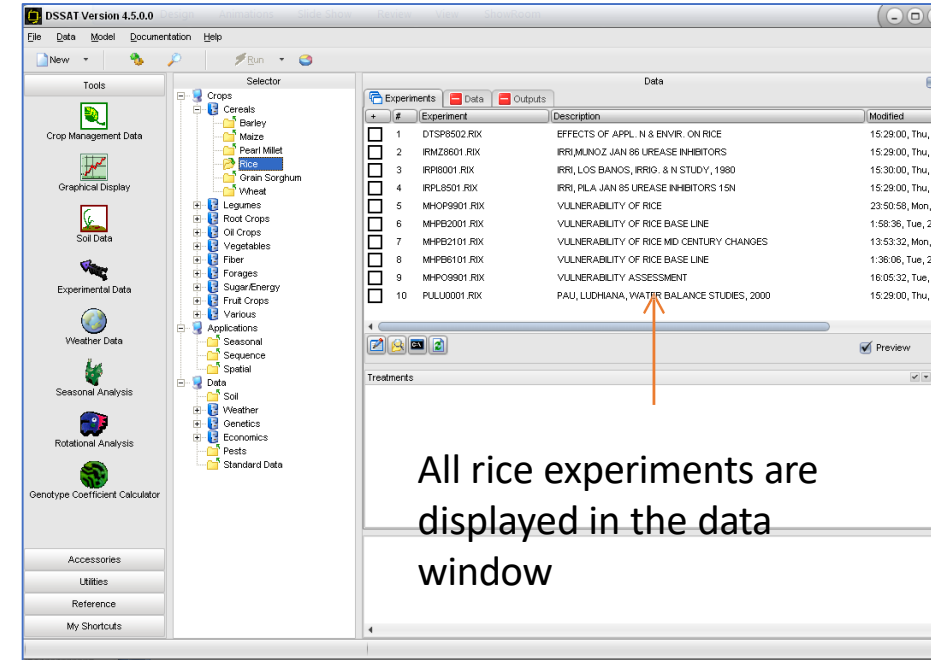

# To begin rice model first click on cereals

From DSSAT 45 main window

Select -crops

Select -cereals

Select -rice

**There are six input files required for simulating rice model**

1. Weather file
2. Experimental file
3. Average (A) file (Growth)
4. Time (T) file (Growth)
5. Cultivar file
6. Soil file

Weather files are stored in  
C:\DSSAT45\Weather folder

Path of Rice Experimental files C:\DSSAT45\Rice  
This includes FILEX, FILE A and FILET

Path of Rice genotype files C:\DSSAT45\Genotype

# Opening the A file from data window

The screenshot shows the DSSAT Version 4.5.0.0 software interface. The main window has a menu bar (File, Data, Model, Documentation, Help) and a toolbar. On the left is a 'Tools' panel with icons for Crop Management Data, Graphical Display, Soil Data, Experimental Data, Weather Data, Seasonal Analysis, and Rotational Analysis. In the center is a 'Selector' panel with a tree view of data categories: Crops (Cereals: Barley, Maize, Pearl Millet, Rice, Grain Sorghum, Wheat; Legumes; Root Crops; Oil Crops; Vegetables; Fiber; Forages; Sugar/Energy; Fruit Crops; Various; Applications; Seasonal; Sequence; Spatial), Data (Soil, Weather, Genetics, Economics, Pests, Standard Data), and a 'Data' window on the right. The 'Data' window has tabs for Experiments, Data, and Outputs. Under the 'Data' tab, 'Experimental Data' is selected, showing a list of files: 'C:\DSSAT45\rice\DTSP8502.RIA' (checked) and 'C:\DSSAT45\rice\DTSP8502.RIT'. An orange arrow points from this file to a Notepad window titled 'DTSP8502 - Notepad'. Another orange arrow points from a text box 'Open this file' to the same Notepad window. Below the DSSAT window is another Notepad window titled 'MHOP9901 - Notepad' showing a different data file.

```

An orange arrow points from the selected file in the "Data" window to the "Notepad" window. A text box with the text "Open this (T) file" is also present, pointing to the "Notepad" window.

The bottom of the DSSAT window shows a status bar with the text: "\*EXP.DATA (T): DTSP8502RI Effects of appl. N & envir. on rice". Below this, it says "File last edited on day 08/28/2003 at 3:51:27 PM". At the bottom, there is a table with the following data:

@TRNO	DATE	T#AD	LAID	RWAD	SWAD	GWAD	LWAD	CWAD
1	85246	-99	-99	-99	-99	-99	125	122

# To Simulate the rice experiment

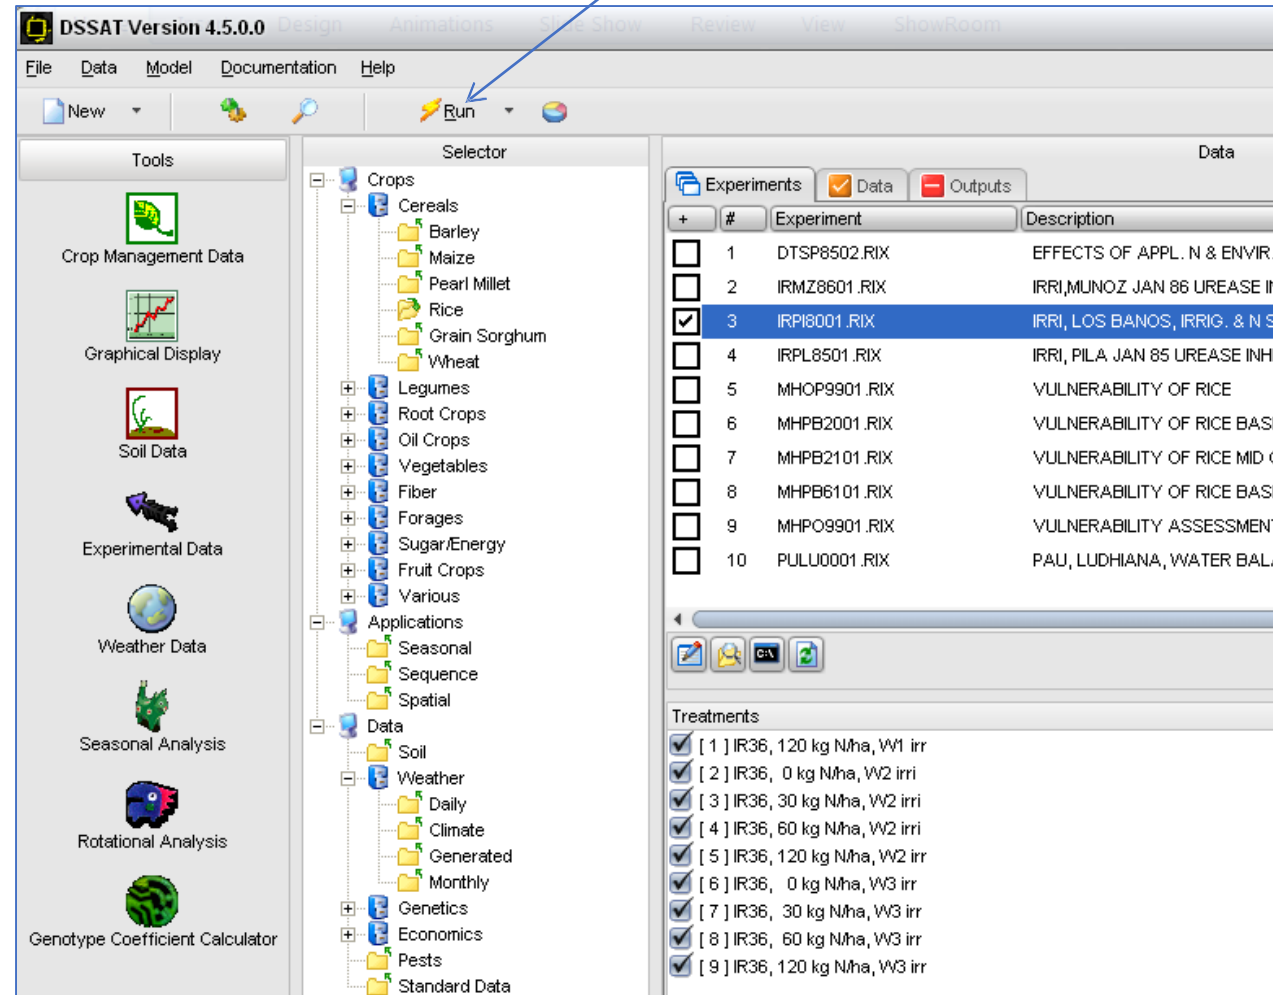

Select experimental file

Click Run icon

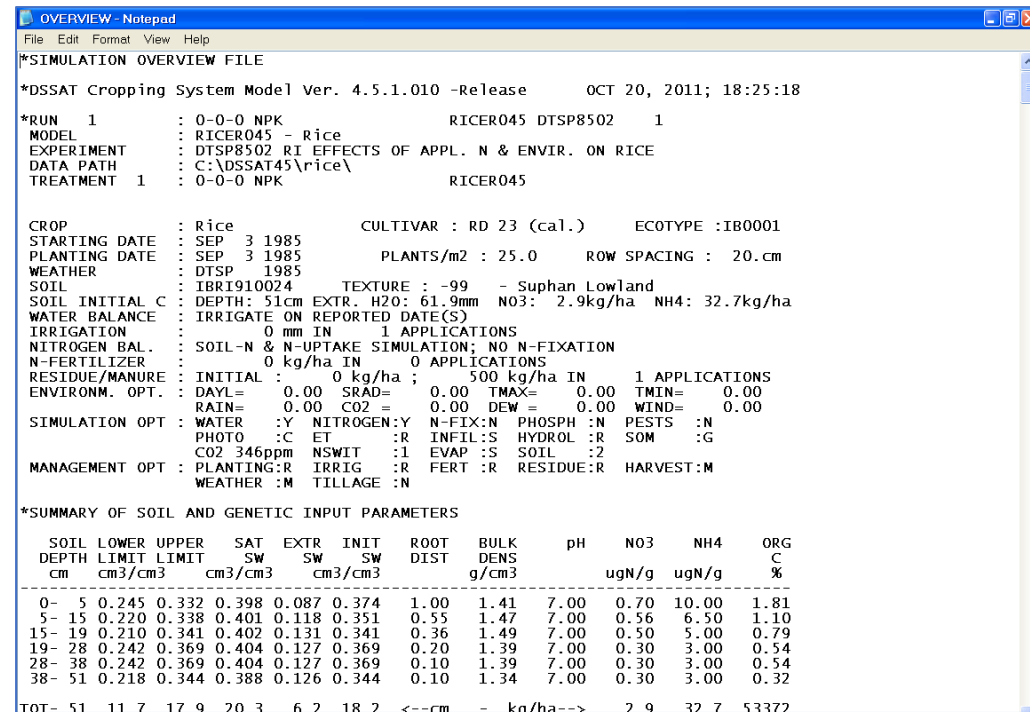

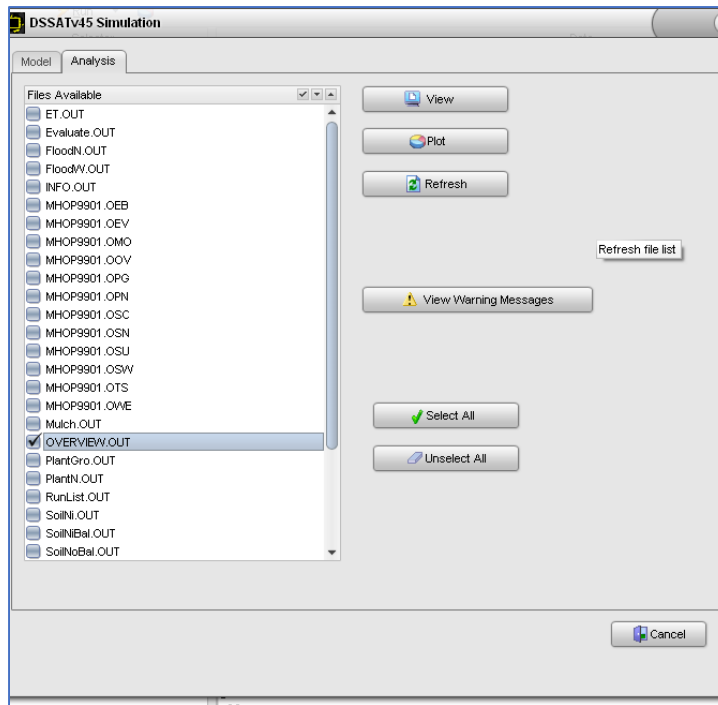

In the next screen

Click run model

Click the run button

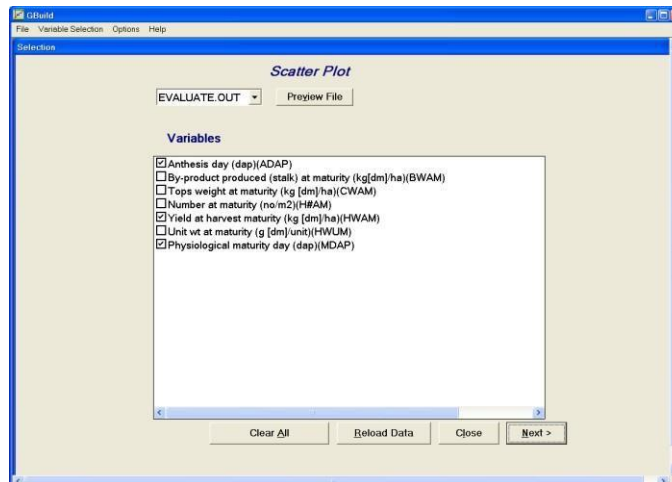

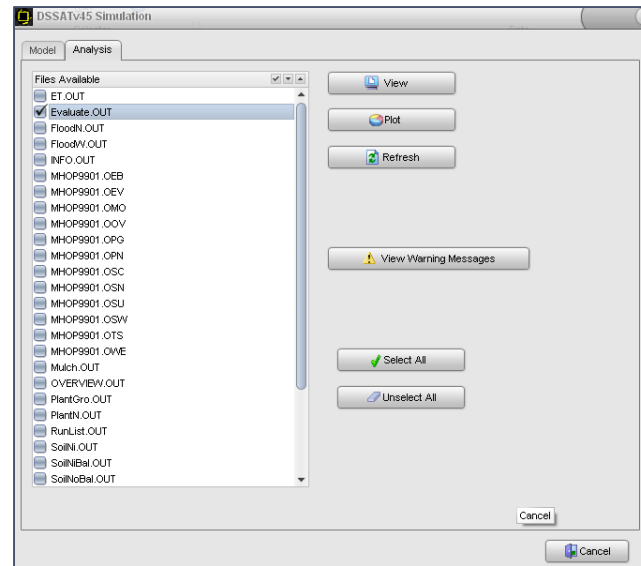

- After selecting the run model and click, the model simulates the rice crop . Under analysis window the model output files are arranged
- From this you select overview. Out and click view. This enable us to see an overview of the model simulation and stage wise weather and crop stress under different conditions
- Just click and view all the .out files one by one

- For evaluating the Model select Evaluate. Out from the output and select plot
- The graphic display activates and shows the phenological events and yield
- Select anthesis (the period during which a flower is fully open and functional) and maturity dates and yield to look into the difference between the observed and simulated values
- Select statistic in the chart screen below

For model evaluation

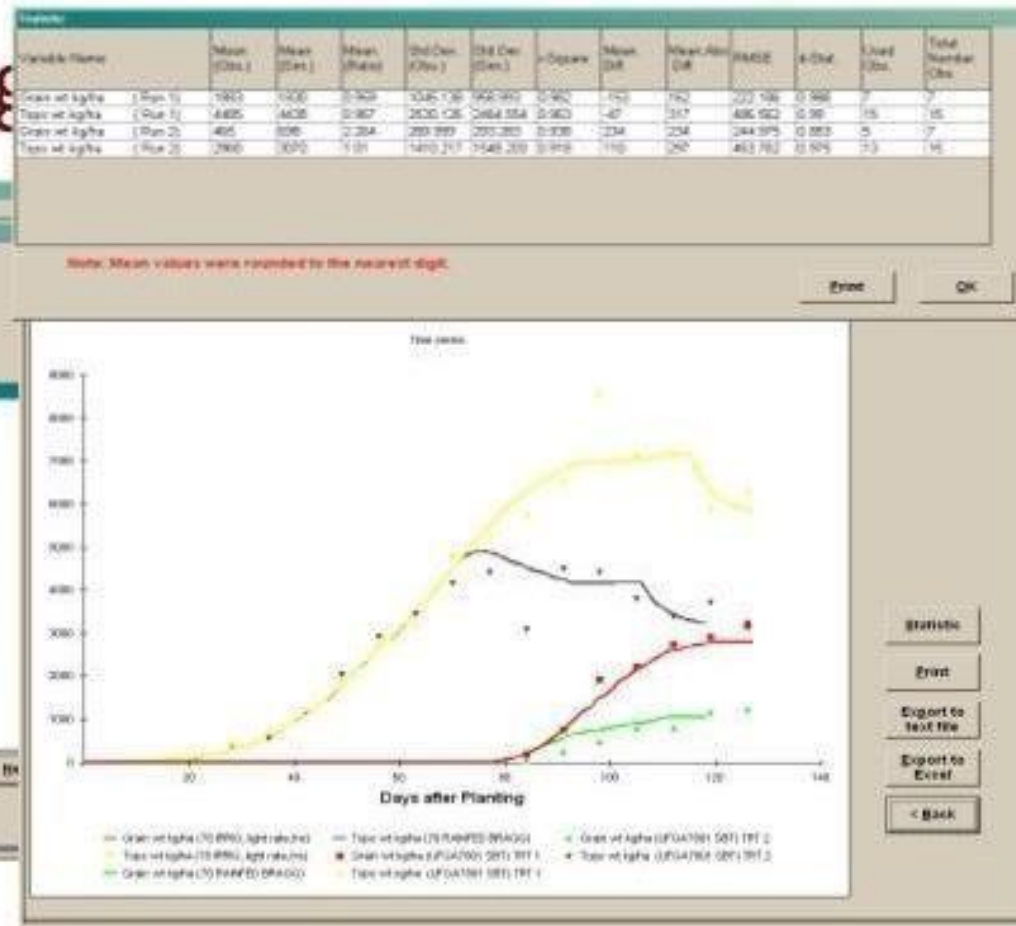

Variable Name	Mean (Obs.)	Mean (Sim.)	Mean (Ratio)	Std.Dev. (Obs.)	Std.Dev. (Sim.)	r-Square	Mean. Diff.	Mean.Ab Diff.	RMSE	d-Stat.	Used Obs.	Total Number Obs.

Name	Genetic coefficients Description
(P1)	Time period (expressed as growing degree days [ GDD] in °C over a base temperature of 9 °C) from seeding emergence during which the rice plant is not responsive to change in photoperiod.
(P2O)	Critical photoperiod or the longest day length (in hours) at which the development occurs at a maximum rate.
(P2R)	Extent to which phasic development leading to panicle initiation is delayed for each hour increase in photoperiod above P20.
(P5)	Time period in GDD °C) from beginning of grain filling (3 to 4 days after flowering) to physiological maturity with a base temperature of 9 °C.
(G1)	Potential spikelet number coefficient as estimated from the number of spikelets per g of main culm dry weight at anthesis.
(G2)	Single grain weight (g) under ideal growing conditions, i.e. non limiting light, water, nutrients, and absence of pests and diseases.
(G3)	Tillering coefficient (scalar value) relative to IR64 cultivar under ideal conditions.
(G4)	Temperature tolerance coefficient. Usually 1.0 for varieties grown in normal environments.
